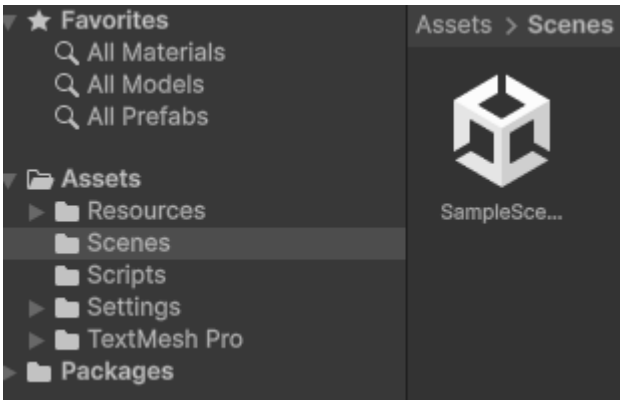
Climate bench Quiz
Unity project user guide

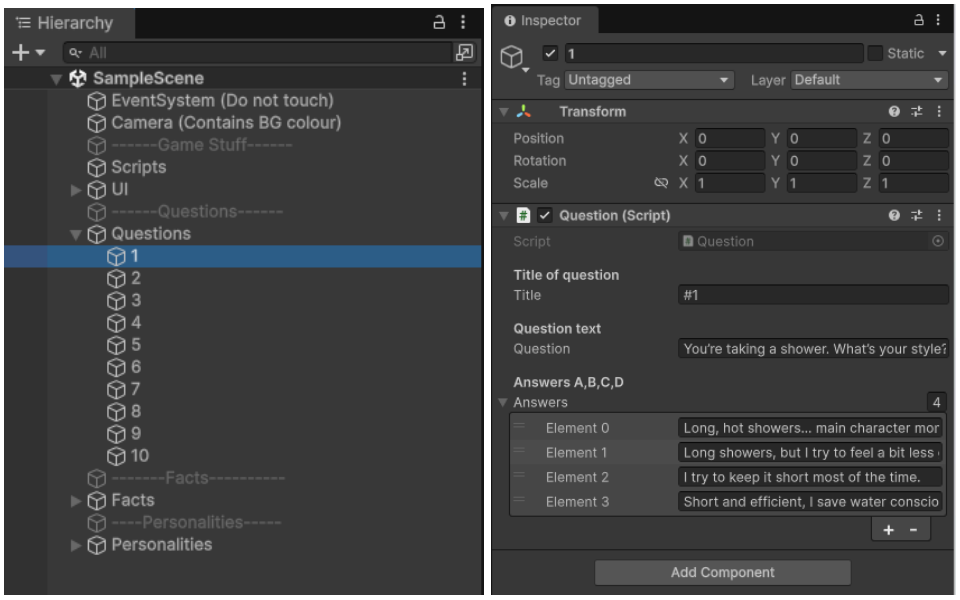
Make sure the editor layout is set to default
(If the editor layout is not default you can go to the window tab at the top of the editor and set it to default. “Window→Layout→Default”

1. Opening the correct scene



If you are at a blank page when opening the project, fear not. go to the Project tab at the bottom of the editor and look for “Scenes” under assets. Click on SampleScene (should be the only scene) and open it.

2. Changing questions

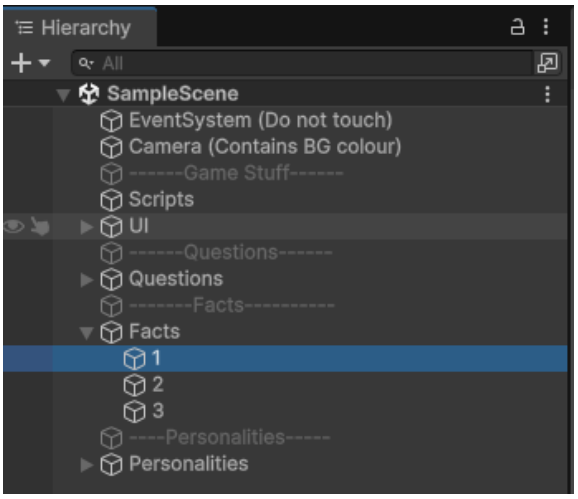


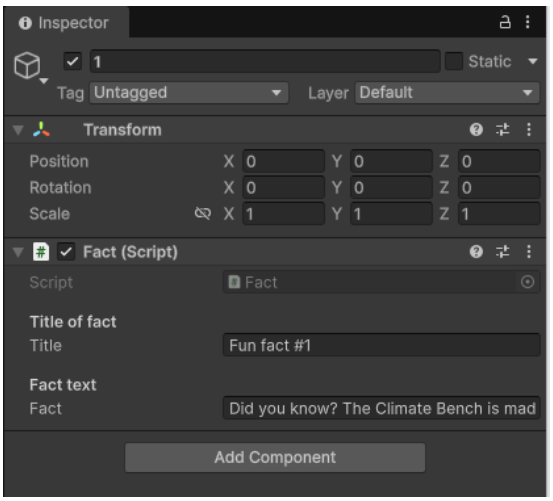
In the Hierarchy tab on the left. Go to the “Questions” object. Underneath the question object there are individual “question” objects (numbered 1-10). Select one of these objects to alter

the question text. To alter the text replace the text in the “Question (Script)” component tab in the Inspector tab on the right. The answers are in a list with elements from 0-3 (0,1,2,3), each element corresponds to answers (a,b,c,d).

Altering the amount of questions is as simple as adding or removing question objects (they don’t need to be numbered in the hierarchy, you can give them whatever name you want). The important thing is that they contain a "Question (Script)” component.

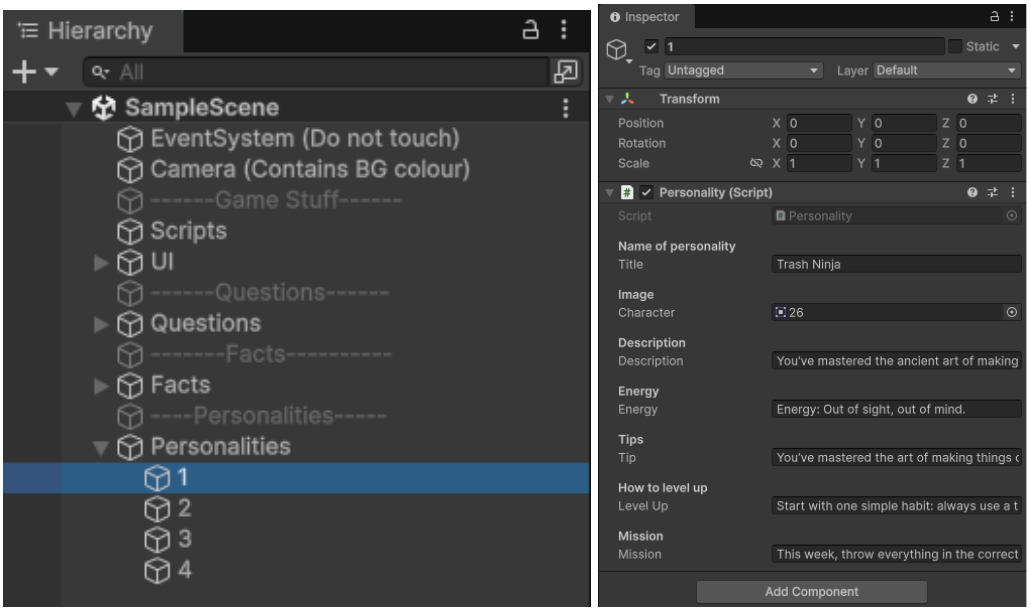
3. Changing fun facts





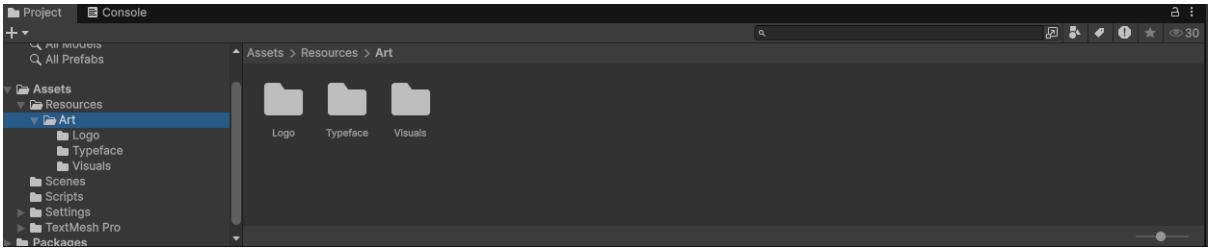
In the Hierarchy tab on the left. Go to the “Facts” object. Underneath the fact object there are individual “fact” objects (numbered 1-3). Select one of these objects to alter the fact text. To alter the text, replace the text in the “Fact (Script)” component tab in the Inspector tab on the right. You can increase or decrease the number of facts by adding or removing fact objects (just make sure they have a “Fact (Script)” component.

4. Changing personalities.

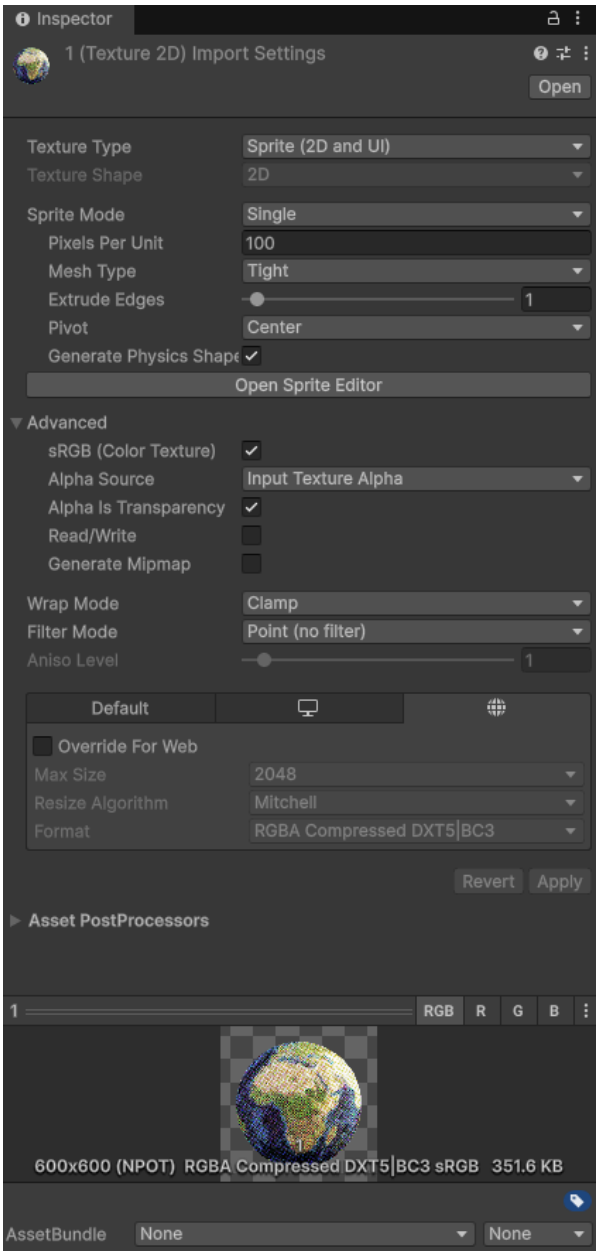


In the Hierarchy tab on the left. Go to the “Personalities” object. Underneath the Personalities object there are individual “personality” objects (numbered 1-4). Select one of these objects to alter the personality text or image. To alter the text, replace the text in the “Personality (Script)” component tab in the Inspector tab on the right. To alter the personality image, click on the image and select an object from the assets.

5. Adding assets/images



If you want to use a new image/asset, you must first add it to the project by dragging it into the “Project” tab at the bottom of the screen (this is a representation of your PC’s file system by the way, so you can also add things via explorer).



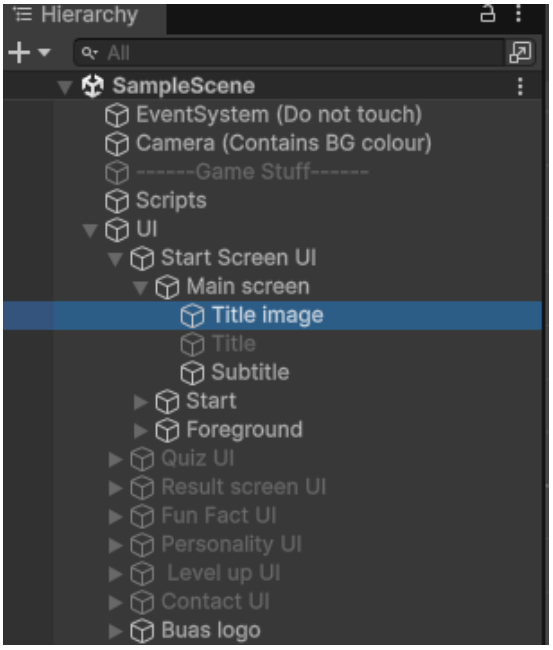
When selecting an imported image you should see something like this on the right side of your screen. Make sure the *texture type* is set to “Sprite (2D and UI)”. *Sprite mode* should be set to “Single”.

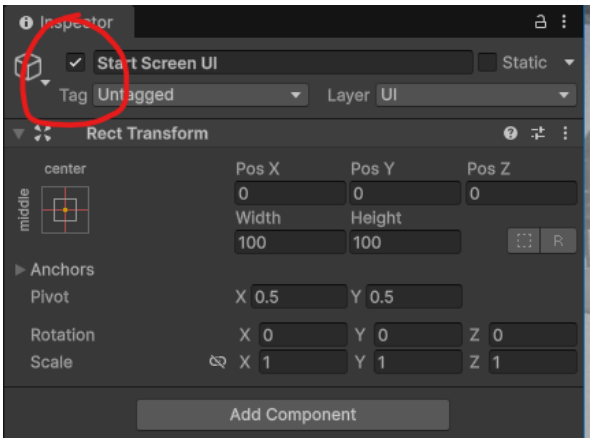
‘

Filter mode should be set to “Point (no filter).

Hit “Apply” to save settings for the image.

6. UI and visuals





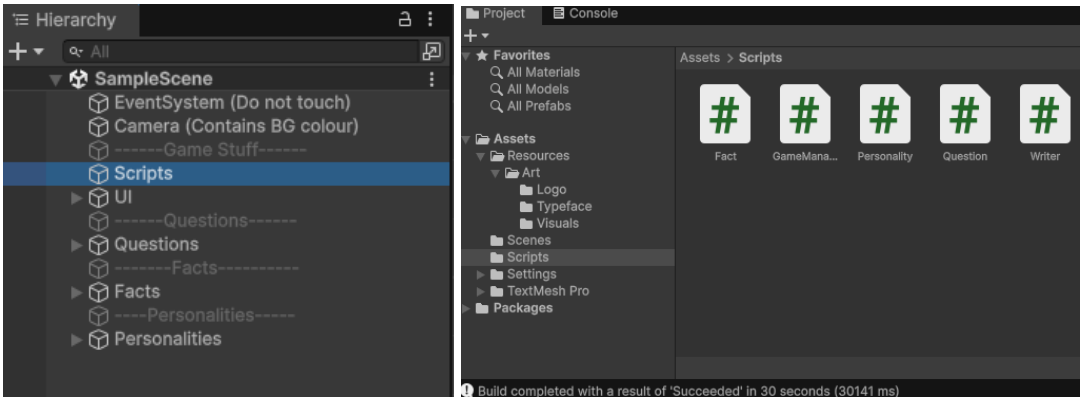
In the Hierarchy tab on the left you can find the various UI elements under the “UI” object. Some of these elements won’t be visible when selected because they are disabled by default. You can check the box next to the object name to enable and disable it the inspector tab on the right.

The game code enables and disables these elements in order to “change screens”, so make sure the start screen is enabled and *all* the rest of the screens are disabled when you are done making changes.

Elements can be moved and scaled by clicking on them. On the left you have a variety of transform options such as *moving, rotating* and *scaling.* Alternatively you can also do this

under the transform component in the inspector window. (Note that Unity is a 3D program, so objects closer to the camera will be rendered in the foreground, the *Z*-axis is the depth and the lower it is the further an object will be from the camera.)

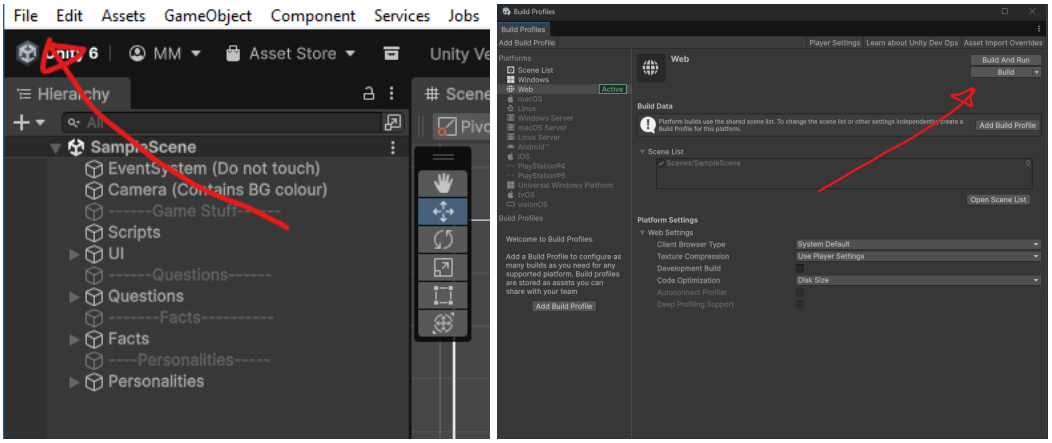
7. Scripts and gamecode



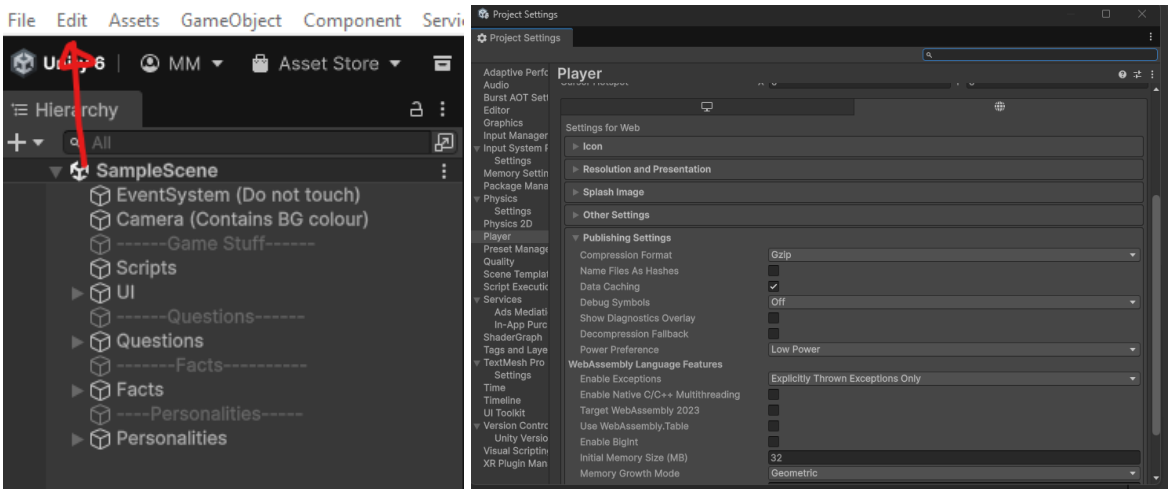
Scripts are located in the “Scripts” object. Unity uses C# code. This guide will not go into depth about the code. But if you’d like to make changes i’ll leave a link to the Unity Scripting manual here: https://docs.unity3d.com/ScriptReference/ , It contains information on all the Unity specific code, otherwise for more general things look at reference for C# code.

There are 2 main scripts in this project. *GameManager* and *Writer,* GameManager handles most of the logic code such as activating and deactivating screens, keeping score and storing references to question-, fact- and personality-objects. Writer is a script for altering text and images on each screen and contains direct references to UI elements.

8. Building a project



In order to build a project. Go to File→Build profiles and open the build profiles tab. In the build profiles tab, make sure the active platform is “Web”. Click build to to build the project to a folder.



To change compression format for the build, go to Edit→Project settings and open the project settings tab. In the project settings tab, look for “Player”. In the Player tab look for “Compression format”. There are 3 options. Gzip, Brotli and “no compression”. If your server can’t handle compressed files, try building without compression.
